Abstract—With the surge in digital content, personalized recommendation systems have become vital for enhancing user engagement, particularly in movie streaming platforms. This paper introduces a hybrid movie recommendation system that combines content-based and collaborative filtering approaches to deliver tailored movie suggestions. Utilizing The Movie Database (TMDB) dataset, the system employs advanced techniques, including TF-IDF vectorization, cosine similarity, and Bayesian rating averaging, to boost recommendation relevance and accuracy. Key metrics such as diversity, novelty, and Normalized Discounted Cumulative Gain (NDCG) were used to evaluate and compare model performance. The hybrid model proved effective in balancing accuracy and diversity, addressing common challenges like the cold start and data sparsity issues. Developed in Python with scalable data-processing frameworks, the system creates a responsive recommendation experience that adapts dynamically to user preferences in real time.

Keywords— Hybrid recommender system, Content-based filtering, Collaborative filtering, TF-IDF vectorization, Cosine similarity, Bayesian rating, Data sparsity, NDCG.

I. INTRODUCTION

The rapid expansion of digital content across domains, from e-commerce to entertainment, has created a pressing need for efficient information filtering mechanisms. Recommender systems (RS) have become essential tools for helping users navigate massive data pools, particularly in competitive sectors like movie streaming, where platforms such as Netflix and Amazon Prime aim to retain engagement by offering tailored content suggestions aligned with individual preferences [1].

Recommender systems employ three primary approaches: content-based filtering, collaborative filtering, and hybrid models. [2] Content-based filtering recommends items similar to those a user has previously interacted with, focusing on specific item attributes like genre or actor—a method well-suited when comprehensive metadata is available [3, 4]. Collaborative filtering (CF), on the other hand, identifies patterns in user interactions, assuming that users who shared preferences in the past will do so in the future. CF methods include user-based and item-based models, each of which compares users or items based on shared ratings [5]. However, CF systems face notable challenges, such as data sparsity, scalability issues,

and difficulties with new users or items (the “cold start” problem) [6].

To mitigate these limitations, hybrid recommender systems have emerged, combining content-based and collaborative filtering to improve recommendation accuracy and reduce reliance on either user or item data alone. These systems have shown particular success in addressing cold start issues and data sparsity in movie recommendation systems (MRS). By integrating data sources ranging from explicit ratings to implicit behaviors, such as viewing habits, they enhance the robustness and relevance of recommendations [3]. Hybrid MRS can even incorporate sentiment analysis from user reviews, capturing nuanced preferences that surpass simple numerical ratings [7].

With advances in technology, hybrid systems now integrate sophisticated machine learning and deep learning techniques to refine user and item modeling further. Recent studies highlight the effectiveness of deep learning models—such as autoencoders and neural networks—in extracting complex patterns from vast, multi-dimensional datasets, including user reviews and multimedia content. These models allow hybrid systems to process large volumes of data in real-time, producing highly accurate and contextually relevant recommendations [8]. Using big data platforms like Spark, these systems maintain high responsiveness, even under heavy usage.

Evaluating recommender systems requires a multi-faceted approach, with metrics focused on both system-centric accuracy and user-centric satisfaction. The Framework for Evaluating Recommender Systems (FEVR) offers a structured methodology that combines offline and real-world feedback to optimize performance iteratively and meet users’ needs in practical scenarios [6, 8].

In the movie domain, hybrid approaches that blend collaborative and content-based filtering techniques have proven highly effective. They often employ layered architectures that support data-intensive operations using big data technologies and machine learning models, thus balancing accuracy with efficiency. Studies suggest these hybrid systems outperform traditional models by enhancing scalability and responsiveness—essential factors for real-time platforms where user retention depends on delivering timely, personalized recommendations [3–5]. Hybrid MRS ultimately offer a multi-

dimensional recommendation experience, combining collaborative insights with content-driven suggestions that elevate user engagement and satisfaction.

As the demand for personalized content continues to grow, hybrid recommender systems—enhanced by deep learning and big data capabilities—are setting new standards for accuracy and user experience. By combining collaborative filtering, content-based methods, and advanced machine learning, today’s hybrid MRS provide an engaging content discovery experience that dynamically adapts to users’ evolving preferences in an information-rich world.

II. METHODOLOGY

A. Overview

This paper proposes an enhanced hybrid movie recommendation system combining content-based and collaborative filtering techniques. The system aims to deliver personalized movie suggestions by exploiting both the intrinsic properties of movies and user interaction data. The methodology integrates TF-IDF vectorization, cosine similarity, and Bayesian rating averaging, among other advanced techniques, to improve recommendation accuracy, user satisfaction, and performance across diverse scenarios. The evaluation of the system is carried out using key metrics such as diversity, novelty, and NDCG (Normalized Discounted Cumulative Gain). These metrics measure the system’s ability to generate a wide range of recommendations while maintaining high accuracy and user relevance. The proposed system aims to bridge the limitations of both individual recommendation approaches by developing a robust hybrid framework.

B. Data Collection and Preprocessing

The dataset employed in this study is the publicly available The Movie Database (TMDB) dataset[9], which contains detailed movie metadata (e.g., movie titles, genres, keywords, overviews) along with user ratings. This dataset is processed through a series of steps to ensure the quality of recommendations. The movie features, including overviews, keywords, and genres, are combined into a single feature set. In the preprocessing stage, the keyword feature is assigned double weight and the genre feature is assigned triple weight to better capture movie relevance. Furthermore, the system utilizes Bayesian rating averaging to normalize user ratings by considering the popularity of the movies and the total number of votes. This method leads to the calculation of a weighted movie rating, which balances the inherent bias of movies with fewer ratings and offers more equitable comparison across movies. The weighted rating is computed as follows:

$$\text{Weighted Rating} = \frac{v}{v + m} R_{\text{avg}} + \frac{m}{v + m} C \quad (1)$$

where v denotes the number of votes for a movie, m is the minimum number of votes required to be considered, R_{avg} is the average movie rating, and C represents the global average rating across the entire dataset.

C. Recommendation Models

1) *Content-Based Recommender*: For content-based recommendations, the system leverages TF-IDF vectorization to represent each movie based on its features (overview, genres, keywords). This approach transforms textual information into numerical feature vectors that capture the importance of words in relation to a particular movie. The cosine similarity between these feature vectors is computed to measure the similarity between movies, which then enables the generation of personalized recommendations by identifying top-N most similar movies based on their content.

2) *Collaborative Filtering Recommender*: In the collaborative filtering component, movie recommendations are generated based on user interactions, specifically focusing on ratings. A user-item rating matrix is constructed where each row corresponds to a user and each column corresponds to a movie. For each movie, a weighted average rating is computed using Bayesian rating averaging to adjust for the popularity bias. The system then computes the cosine similarity between movies based on this rating matrix, which reflects how similar the preferences are between users, enabling the recommendation of movies based on collaborative information.

3) *Hybrid Recommender*: The hybrid model integrates both content-based and collaborative filtering techniques to improve recommendation quality. To combine the outputs of the two models, we introduce dynamic weighting for both the content-based and collaborative components. The recommendation score for each movie is calculated by taking a weighted average of the similarity scores derived from both models. The formula for the hybrid recommendation score is as follows:

$$\text{Hybrid Score}(i) = \alpha \times \text{Content Similarity}(i)$$

$$+ (1 - \alpha) \times \text{Collaborative Similarity}(i) \quad (2)$$

where α is the weight assigned to the content-based model. This hybrid approach balances the advantages of content-based filtering (which relies on movie features) and collaborative filtering (which considers user behavior), thus overcoming the weaknesses of each method individually.

D. Evaluation Metrics

The evaluation of the recommender system is performed using three key metrics: diversity, novelty, and NDCG. Diversity is assessed by calculating the variety of genres in the recommended list of movies. This is measured by counting the number of unique genres in the top-N recommended movies. Novelty, on the other hand, is quantified by evaluating the average popularity of recommended movies, where lower popularity indicates more novel recommendations. Finally, the NDCG metric measures the ranking quality of the recommended movies, considering both their relevance and position in the list. The formula for NDCG is defined as:

$$\text{NDCG}(k) = \frac{\text{DCG}(k)}{\text{IDCG}(k)} \quad (3)$$

figure/methodology.png

Figure 1: Overview of the movie recommendation system methodology

where DCG is the Discounted Cumulative Gain at rank k , and IDCG is the Ideal DCG, representing the best possible ranking of movies.

E. Results and Analysis

For the system's performance evaluation, a series of experiments are conducted by randomly selecting a subset of movies from the TMDB dataset. For each movie in the test set, recommendations are generated using the content-based, collaborative, and hybrid models. The diversity, novelty, and NDCG metrics are computed for each model, and the results are averaged over all test cases. To visualize the performance, heatmaps are generated to compare the average performance across models and metrics. This helps in understanding the trade-offs between the models and demonstrates the superior performance of the hybrid model in combining content-based and collaborative information.

F. Complexity Analysis

The content-based recommender involves TF-IDF vectorization and cosine similarity, which results in an $O(n^2)$ complexity, where n is the number of movies. The collaborative filtering model also incurs a complexity of $O(n^2)$, as it involves computing the cosine similarity from the user-item rating matrix. The hybrid model, which combines the results of both content-based and collaborative approaches, maintains the same complexity of $O(n^2)$. Therefore, while the hybrid model combines two models, its computational complexity remains manageable due to the efficient implementation of similarity calculations.

G. Implementation Details

The entire system is implemented in Python, utilizing libraries such as Pandas for data manipulation, Scikit-learn for modeling, and Matplotlib/Seaborn for data visualization. The system is designed to handle large datasets efficiently and

is built within a Jupyter Notebook environment for ease of experimentation, parameter tuning, and result visualization.

III. RESULTS

In this section, we present the performance of various recommendation approaches for suggesting movies similar to *The Dark Knight*. The three approaches used for comparison are content-based, collaborative, and hybrid recommendation systems. The results are shown in terms of evaluation metrics, movie recommendations, and qualitative analysis.

A. Evaluation Metrics

We evaluate the performance of each recommendation approach using key metrics: similarity, novelty, diversity, and normalized discounted cumulative gain (NDCG). As shown in Figure 2, collaborative filtering achieves the highest diversity (28.370) and novelty (0.143) scores. However, its similarity score is moderately ranked at 0.995. Content-based filtering excels in novelty with a score of 0.087 but shows lower diversity. The hybrid approach provides a balanced performance across all metrics, with similarity, diversity, and novelty scores of 0.385, 26.160, and 0.095, respectively. Notably, all approaches achieve perfect NDCG scores of 1.00.

figure/metrics.png

Figure 2: Comparison of evaluation metrics across different recommendation approaches for similarity, novelty, diversity, and NDCG.

B. Movie Recommendations

Table I presents the top movie recommendations for *The Dark Knight* based on content-based, collaborative, and hybrid approaches, along with their corresponding similarity scores. The content-based approach recommends movies such as *The Dark Knight Rises* and *Batman Begins*, which have similarity scores of 0.6805 and 0.6706, respectively. The collaborative approach identifies movies such as *Inception*, *The Lord of the Rings: The Return of the King*, and *Forrest Gump*, all with near-perfect similarity scores above 0.99. The hybrid approach attempts to balance relevance with diversity, recommending movies like *The Dark Knight Rises* and *Batman Begins* with similarity scores of 0.6000 and 0.5714.

Table I: Recommendations for "The Dark Knight"

Recommendation Type	Movie Title	Similarity Score
Content-Based	The Dark Knight Rises	0.6805
Content-Based	Batman Begins	0.6706
Content-Based	Batman v Superman: Dawn of Justice	0.5752
Content-Based	Batman & Robin	0.5459
Content-Based	Batman Returns	0.5399
Collaborative	Inception	0.9998
Collaborative	The Lord of the Rings: The Return of the King	0.9997
Collaborative	Forrest Gump	0.9997
Collaborative	The Lord of the Rings: The Fellowship of the Ring	0.9997
Collaborative	Star Wars	0.9996
Hybrid	The Dark Knight Rises	0.6000
Hybrid	Batman Begins	0.5714
Hybrid	Inception	0.4000
Hybrid	The Lord of the Rings: The Return of the King	0.3664
Hybrid	Forrest Gump	0.3428

C. Comparison Across Different Recommendation Approaches

The similarity scores across different approaches highlight the advantages and limitations of each recommendation method. The content-based method achieves the highest similarity scores, suggesting movies closely aligned with *The Dark Knight*, but it lacks diversity. The collaborative approach enhances diversity by recommending movies across various genres, such as *The Lord of the Rings* and *Star Wars*, and this leads to higher diversity scores. The hybrid method strikes a balance between content relevance and genre diversity.

figure/recommendation_comparison.png

Figure 3: Comparison of similarity scores across different recommendation approaches for movies similar to *The Dark Knight*. Visualizations of recommendation system performance metrics across content-based, collaborative, and hybrid approaches.

D. Strengths and Challenges

Each recommendation approach has its strengths and challenges:

- **Ranking Quality:** All methods achieve perfect ranking quality with an NDCG score of 1.00.
- **Diversity:** The collaborative and hybrid approaches excel in diversity, providing genre variety.
- **Novelty:** The hybrid method demonstrates robustness, combining content-based and collaborative features.

However, novelty scores remain relatively low across all methods, ranging from 0.143 for collaborative filtering to 0.087 for content-based filtering, suggesting potential areas for improvement.

IV. CONCLUSION

This study proposed a hybrid movie recommendation system that successfully combines content-based and collaborative filtering methods to improve recommendation accuracy, diversity, and user satisfaction. The system's use of TF-IDF vectorization, cosine similarity, and Bayesian averaging enhances its capacity to generate relevant recommendations by addressing data sparsity and cold start issues inherent in traditional approaches. The hybrid model outperforms individual content-based and collaborative methods by balancing genre diversity and recommendation accuracy, making it suitable for large-scale, real-time applications in the movie streaming domain. The system's effectiveness is validated through comprehensive evaluations, showing its potential as a robust solution in personalized content delivery.

V. FUTURE WORK

Enhancements to the hybrid recommendation system can be achieved by integrating advanced deep learning techniques, enabling intricate user preferences and complex content characteristics to be captured more effectively. Sentiment analysis from user reviews can provide deeper insights beyond basic ratings. Expanding support for diverse multimedia formats, along with implementing real-time big data processing, can

further improve scalability and responsiveness. These enhancements collectively aim to create a highly adaptive, personalized recommendation experience that aligns dynamically with evolving user needs in digital environments.

VI. ACKNOWLEDGMENT

We extend our heartfelt gratitude to Dr. Nursadul Mamun for his invaluable guidance, support, and encouragement throughout the development of this project. His expertise and mentorship were instrumental in shaping our research and bringing this work to completion.
